INTRODUCTION

This paper documents the distribution and status of *Nephelaphyllum pulchrum* Bl. (Figs. 1, 2) in Singapore. *Nephelaphyllum* is a small genus of about 11 recognised species distributed from China, Japan, India, and throughout Southeast Asia (Comber, 1990 & 2001; Seidenfaden & Wood, 1992; Cootes, 2001; Govaerts et al., 2005). Two species are recorded from Peninsular Malaysia, of which only *Nephelaphyllum pulchrum* occurs in Singapore (Keng et al., 1998; Tan et al., 2008; Chong et al., 2009).

The generic name *Nepelaphyllum* is derived from the Greek words “nephele”, which means cloud, and “phyllon”, which means leaf, referring to the hazy, marbled look of the leaves (La Croix, 2008) (Figs. 1, 2). The specific epithet *pulchrum* derived from the Latin “pulcher”, meaning beautiful, aptly describes this attractive species with purplish, marbled leaf blades. *Nepelaphyllum pulchrum* is also the type species of the genus (Cootes, 2001). Members of the genus are terrestrial, usually possessing fleshy leaves and thick rhizomes that creep along the forest floor.

PAST AND PRESENT RECORDS

Nepelaphyllum pulchrum is a terrestrial orchid species, with fleshy, creeping rhizomes (Comber 1990, 2001; Keng et al., 1998; Go & Hamzah, 2008) (Figs. 1, 2). Pseudobulbs are slender and curved at the tip, dull purple, and about 2–3 cm long. The leaf blades are triangular-ovate, basally cordate, with a tip that is acuminate and blunt, 4–10 cm by 2.5–6 cm, light brown or yellowish green with dark blotches on the upper surface and flushed purple on the underside. They are held erect by a very short leaf stalk. The inflorescence develops at the tip of new pseudobulbs, is about 8 cm long with a 1-cm long sheath, and bears flowers close together (Fig. 3). Flowers vary from being almost completely white to very pink, are non-resupinate, with linear and acute sepals and petals that are 1.3–2 cm long and 0.3–1.8 cm broad, downward deflexing, and pale green with purple veins (Fig. 4). The lip is upright, entire, ovate, pale yellow, and fleshy, 1.6–2 cm by 1.1–2 cm, shortly spurred, with five longitudinal rows of fine yellow hairs in the middle, tapering into three ridges near the tip. The column is short and broad and about 5 mm long. This species is distributed from Myanmar, Cambodia, Vietnam, Thailand, south to Peninsular Malaysia, Singapore, Sumatra, Java, and Borneo. This orchid grows in moist localities of lowland to mid-mountain forests.

In Singapore, this species has been collected from Bukit Mandai and Nee Soon Swamp Forest (NSSF; Table 1) (Keng et al., 1998) and is listed as “Critically Endangered” (Tan et al., 2008; Chong et al., 2009).

On 9 Sep.2010, this orchid was encountered by WFA, CKY, and JSYT at Nee Soon Swamp Forest, growing under the thick canopy on swampy ground covered with a thick layer of leaf litter. The orchid was growing and creeping up the trunk of an unidentified tree (Fig. 1). In drier conditions, this species seldom climbs, but rather, it creeps along the forest floor among leaf litter. However in moist conditions such as in swamp forests [e.g., Nee Soon Swamp Forest, Panti Forest Reserve (Peninsular Malaysia), and in Bako National Park (East Malaysia)] and in highland areas [e.g., in Cameron Highlands (Peninsular Malaysia), Fraser’s Hill (Peninsular Malaysia), and Gunung Serapi (East Malaysia)], the increased humidity allows this species to climb a few metres up tree trunks (AFSLL, pers. obs.).

Another individual was encountered growing amongst leaf litter (Fig. 2) at the NSSF. At first sight, the brown-mottled leaves of this terrestrial orchid blend in very well with the surrounding dead leaves. As the usual habit of *Nepelaphyllum pulchrum* is that of a herbaceous terrestrial creeper, the leaves are often borne close to the ground. This could possibly serve as camouflage for the thinly succulent foliage of this species from grazing herbivores, by disrupting the outline of its leaves against the leaf litter (Givnish, 1990). Another hypothesis is that the mottling could serve to mimic damage caused by leaf miners (moth caterpillars that feed inside the leaf blades) so as to deter actual

oviposition by leaf miner moths (Smith, 1986). The attractive, mottled leaves give this orchid species its horticultural potential. As it grows naturally under deep shade, it is suitable as an indoor plant as long as the growing medium is kept moist. However, this orchid is currently not employed horticulturally and should be propagated and conserved *ex situ* in the face of an uncertain future of NSSF as it faces the effects of global warming.

ACKNOWLEDGEMENTS

We would like to express our gratitude to the Chief Executive Officer and staff members of the National Parks Board (NParks) for granting us permission to access and make collections in the Central Catchment Nature Reserve, the herbarium staff of Singapore Botanic Gardens (SING) Herbarium and Raffles Museum of Biodiversity Research, National University of Singapore (SINU) for allowing us access to collections of *Nephelaphyllum pulchrum*, and to How Choon Keat for his assistance in fieldwork. This research was partially funded by the Ministry of National Development Research Fund for the Built Environment through the research grant for the project “Enhancing the Urban Native Biodiversity of Singapore” in collaboration with the NParks.
